

For All 15 Projects

1. Choose your AI model (LLM)

- Pick the AI model you'll use (like GPT-4.1 or Claude) and briefly explain why you chose it. A simple reason like better quality, lower cost, or faster responses is enough.

2. Choose an Agent Framework

- If your project uses AI agents, mention the framework you'll use to manage them. LangGraph is recommended for most projects, while Semantic Kernel is a good choice for .NET/Azure projects.

3. Explain your RAG setup

If you're using RAG, mention:

- Which Vector Database you'll use.
- How you'll split your documents (chunking).
- Which embedding model you'll use.

Just give a clear overview of how your AI will find information.

4. Monitor your AI

- Use a tool like Langfuse to track AI requests, response times, errors, and API costs. This makes it much easier to debug and improve your application.

5. Plan your deployment

Explain how you'll deploy your project. Include:

- Automated testing
- CI/CD
- Docker
- Your hosting platform (Azure, AWS, Vercel, etc.)

Show that your project can be deployed, not just developed.

6. Think about security

- Add a short section explaining how you'll protect user data and secure your

application (authentication, encryption, HTTPS, permissions, etc.).

For Conditional Projects with BLOCKING Issues

Projects with **BLOCKING** conditions should not begin implementation code until each blocking issue is resolved in writing and submitted for review. Blocking conditions are structural gaps that will require the most expensive forms of rework if addressed mid-development: LLM misalignment, RAG pipeline design changes, and agent framework migration all require significant code refactoring if changed after development has started.

Strong Concepts, Weak Specifications

project ideas and problem statements are strong, but many pitches don't clearly explain the technical implementation. Make sure to specify which technologies you'll use **so your pitch explains not only what you're building, but also how you'll build it.**

Agent Framework Naming: Only One Project (**SentinelAI**)

SentinelAI is the only project to name a specific agent framework (Microsoft Semantic Kernel). mention the specific agent framework you'll use (such as LangGraph or Semantic Kernel). Naming your framework makes your technical plan clearer and more complete.

LLM Selection

Choose a specific LLM for your project **instead of using general terms like "GPT-based models" or "OpenAI or Gemini."** Briefly explain **why you selected it**, considering factors such as cost, performance, speed, or language support.

Egyptian/Arabic Localization

Supporting Arabic and targeting the Egyptian market can give your project a strong competitive advantage. If it fits your idea, **consider adding localization features such as Arabic language support or Egyptian-specific content**, and clearly highlight them in your pitch to make your solution more relevant and impactful.

Security and Observability: Near-Zero Across the Batch

Don't focus only on your AI features also **include a security and monitoring plan. Explain how you'll protect user data** and consider using tools like Langfuse or LangSmith to monitor your AI system, especially if your project handles sensitive information.
